SparkFinance

Project Presentation Brief

Prepared for CA, Manager and Senior Manager review

Purpose	A practical guide to demonstrate the system, explain each module, answer cross-questions and present the current product status honestly.

React	.NET 10	SQL Server	AE + IN
Frontend	**Backend**	**Database**	**Country scope**

Core presentation message

Say this	SparkFinance already manages the operational finance lifecycle. The Chart of Accounts provides the UAE and India accounting foundation. The next phase connects every transaction to double-entry accounting and statutory reporting.

Presentation date: 2 November 2026

Document type: Internal product briefing

1. Executive summary

Opening statement

60-second introduction

SparkFinance is a modular finance-management platform designed for companies operating in the UAE and India. It covers customer sales, vendor purchases, expenses, banking, exchange rates and the Chart of Accounts. The frontend uses React, the backend uses ASP.NET Core services, and SQL Server stores the financial data. The current phase focuses on controlled business-document workflows. The next phase completes automated double-entry posting, ledger reports, authentication and production deployment.

Verified build status

Area	Result	Presentation meaning
Frontend	Build successful	The React application compiles and is demo-ready.
Original backend solution	12 services build, 0 errors	Core service projects compile successfully.
Accounting service	Builds separately, 0 errors	Chart of Accounts works, but start it separately.
Warnings	Package and bundle warnings	Do not call the solution production-ready yet.
Tests	Some logic checks pass; SQL harnesses blocked	Broader automated test and CI work is still required.

Honest positioning

Present this as a strong working finance prototype and accounting foundation. Do not claim that authentication, complete general-ledger posting, statutory reporting or production deployment are finished.

Architecture explanation

- React and Vite provide the user interface and route requests to the relevant service.
- ASP.NET Core services separate sales, purchases, expenses, banking, exchange rates, dashboard and accounting responsibilities.
- The services currently share one SQL Server database. Describe this as modular services, not fully isolated microservices.
- Database validation, unique constraints, row-version concurrency and protected system accounts support financial control.

2. Recommended demonstration plan

Keep the presentation business-first. Show the accounting structure after the operational workflows so the audience understands what will eventually receive the postings.

Order	Module	Time	What to demonstrate
1	Dashboard	2 min	Management totals, branch, date and reporting-currency filters, recent activity.
2	Sales	4 min	Client to estimate to invoice to payment, with credit notes for corrections.
3	Purchases	4 min	Vendor to purchase order to bill to payment, with vendor credits.
4	Expenses	2 min	Direct expense recording, categories, currencies and receipts.
5	Banking	4 min	Accounts, transactions, transfers and reconciliation controls.
6	Exchange rates	2 min	Daily read-only monitoring, source, rate date and status.
7	Chart of Accounts	5 min	AE and India templates, hierarchy, posting/group accounts and protection.
8	Roadmap	2 min	Journal engine, ledger, trial balance, reports, authentication and deployment.

Suggested transition

Narration

I will first show how business documents move through the system, then how payments and banking are controlled, and finally how the new Chart of Accounts provides the accounting structure for UAE and India entities.

Demo principle

- Use existing records and avoid creating too many records live.
- Show one complete sales flow and one complete purchase flow.
- Keep Swagger open as technical evidence, but explain the business screen first.
- If a preview module is opened, label it clearly as the next implementation phase.

3. Sales and purchase lifecycle

Sales modules

Module	How to explain it
Clients	Customer master data: identity, contacts, address and active status. Sales documents refer to this master.
Estimates	Customer quotation workflow. Draft estimates can be sent, accepted, declined and converted into invoices.
Invoices	Customer sales document. It can be previewed, created and issued, after which collections can be tracked.
Payments Received	Records money received from customers and links the collection with the related invoice.
Credit Notes	Reduces an issued invoice for returns, overbilling or commercial corrections.

Sales flow

Client -> Estimate -> Accepted -> Invoice -> Payment Received. Use a Credit Note when a reduction is required.

Purchase modules

Module	How to explain it
Vendors	Supplier master data including location, currencies and active status.
Purchase Orders	Records the intention to purchase. Supports preview, issue and cancellation.
Bills	Records the supplier invoice and payable. A bill can be created from a purchase order.
Payments Made	Records settlement of vendor bills and shows outstanding bill balances.
Vendor Credits	Reduces supplier liability and can be applied against eligible bills.

Purchase flow

Vendor -> Purchase Order -> Bill -> Payment Made. Use a Vendor Credit when the supplier reduces the amount due.

4. Expenses, banking and management visibility

Expenses

The expense module records operating costs that may not use the normal purchase-order flow. It supports categories, currencies, receipts and voiding. Typical categories include travel, utilities, office costs, software and meals.

Banking

Module	Control provided
Bank Accounts	Maintains bank and cash accounts, currency and opening balance.
Bank Transactions	Records money in and money out with draft, posted and cancelled states.
Bank Transfers	Controls transfers between accounts, including sent, received, cancelled and exchange-rate handling.
Bank Reconciliation	Compares book transactions with statements, supports exact matching and prevents duplicate consumption.

Dashboard

- Shows revenue, expenses, payments received, payments made, receivables and payables.
- Supports branch, date and reporting-currency filters.
- Shows recent financial activity for management review.
- Original transaction values remain unchanged; reporting views use reference exchange rates.

CA focus

Emphasize bank reconciliation, outstanding receivables and payables, document status control, credit adjustments and the difference between original transaction currency and reporting currency.

5. Exchange rates and Chart of Accounts

Daily exchange-rate checker

- Read-only reference rates are retrieved from Frankfurter and stored with source and rate date.
- The service performs a scheduled daily check while it is running.
- It catches up after restart and retries failed checks.
- INR to INR is always 1.
- Refreshing the screen reloads saved results; it does not change rates.
- Existing transaction rates remain unchanged.

Correct terminology

Call this an automatic scheduled exchange-rate checker, not an AI agent.

Chart of Accounts

The Chart of Accounts organizes financial records under Assets, Liabilities, Equity, Income and Expenses. The system supports company-specific structures for UAE and India.

Concept	Meaning
Account code	Human-readable accounting identifier used for classification, searching and reporting.
Account name	Business description such as Cash on Hand or Sales Revenue.
Group account	Organizes child accounts and does not receive direct postings.
Posting account	Final account that can receive journal entries.
Control account	Connects a subledger such as receivables, payables, inventory or tax.
System account	Protected account required by the application and not freely editable.
SystemKey	Stable internal identifier that remains reliable even if the visible account code changes.

6. UAE and India accounting structure

37	43	5
UAE standard accounts	India standard accounts	Main account classes

Example hierarchy

Account tree

1000 Assets
1100 Current Assets
1110 Cash on Hand
1120 Bank Accounts
1130 Accounts Receivable

UAE-specific structure

- Input VAT Recoverable under Tax Recoverable.
- Output VAT Payable under Tax Payables.

India-specific structure

- Input and Output CGST.
- Input and Output SGST.
- Input and Output IGST.
- TDS Receivable and TDS Payable.

Controls to demonstrate

- Every account can be viewed in both Tree and Table modes.
- Only ordinary accounts can be edited.
- System and control accounts are protected in both the frontend and backend.
- The setup endpoint is repeat-safe and does not create duplicate template accounts.
- Account codes are unique within a company.

7. Module readiness matrix

Area	Status	How to present it
Dashboard	Live service	Show management totals and recent activity.
Sales documents	Live services	Show the quote-to-cash flow.
Purchase documents	Live services	Show the procure-to-pay flow.
Expenses	Live service	Show direct expense recording and receipts.
Banking	Live service	Show transactions, transfers and reconciliation.
Exchange rates	Live service	Show read-only daily monitoring.
Chart of Accounts	Live service	Show AE/IN templates and protection.
Journal Entries	Preview / roadmap	Explain the planned posting workflow; do not claim completion.
General Ledger	Preview / roadmap	Requires the completed posting engine.
Trial Balance	Preview / roadmap	Will be calculated from posted journals.
Financial and tax reports	Preview / roadmap	UI exists; complete accounting backend is next.
Authentication and users	Final phase	Preview roles exist; complete service enforcement is pending.
Audit history and settings	Partial / roadmap	Present as governance work still being completed.

Important

Do not demonstrate preview modules as completed. Show their navigation only if the audience asks about the roadmap.

8. Questions a CA may ask

Question	Suggested answer
Why use account codes?	Codes classify accounts and make searching and reporting consistent. 1000 is Assets, 2000 Liabilities, 3000 Equity, 4000 Income and 5000 Expenses.
Why also use SystemKey?	The visible code may change, but SystemKey allows the application to keep identifying critical accounts reliably.
Can a group account receive money?	No. Group accounts organize the structure. Only posting accounts receive journal entries.
Why are some accounts not editable?	System and control accounts are protected because changing their type, balance or hierarchy could damage reporting and subledger integration.
How are UAE and India different?	Each company receives a country-specific template. UAE uses VAT; India uses GST and TDS accounts.
Does currency conversion change the original transaction?	No. The original amount is preserved. Reporting views use the applicable reference rate.
Is the General Ledger complete?	The Chart of Accounts foundation is complete. Automated double-entry posting, ledger, trial balance and statements are the next accounting phase.
How will subledgers reconcile?	Receivables, payables, inventory, tax and bank control accounts will be connected to automated postings and reconciliation reports in the next phase.

9. Questions managers may ask

Question	Suggested answer
Why separate services?	Each business area can be maintained independently. Because they currently share one database, the accurate term is modular services rather than fully isolated microservices.
Is authentication complete?	Authentication and final role enforcement are planned for the final phase. Preview roles currently demonstrate Admin, Finance and Viewer behavior.
Is this production-ready?	Not yet. Production readiness requires authentication, audit controls, security-package updates, broader tests, deployment automation and backups.
What prevents conflicting edits?	The backend uses validation, unique constraints, company separation, protected system accounts and row-version concurrency.
What has been tested?	The projects build successfully. Targeted banking matching and payment validation logic checks pass, while database-backed harnesses require the LocalDB test environment to be repaired.
What is the next major milestone?	Connect every issued document, payment, expense and bank transaction to balanced journal entries, then deliver ledger, trial balance and statements.
Can it scale?	The modular design supports gradual scaling, but production hosting, database strategy, monitoring and service boundaries still need formalization.

10. Risks, improvements and roadmap

Known presentation and technical risks

Priority	Item	Required action
High	Authentication is not complete	Add backend identity, authorization and secure session handling.
High	Full accounting posting is incomplete	Build balanced journal generation and posting rules for every source module.
High	Vulnerable package warnings	Upgrade and retest affected cryptography dependencies.
Medium	Accounting service missing from root solution	Add it to SparkFinanceBackend.slnx and update startup documentation.
Medium	Database-backed test harnesses blocked	Repair test LocalDB setup and add repeatable CI tests.
Medium	Shared development database	Design production SQL hosting, migrations, backups and recovery.
Low	Large frontend bundle	Introduce route-level code splitting and lazy loading.

Recommended delivery sequence

- Phase 1: Journal-entry model, posting rules, fiscal periods and period locks.
- Phase 2: Automatic postings from invoices, bills, payments, expenses and banking.
- Phase 3: General Ledger, Trial Balance, Profit and Loss, Balance Sheet and Cash Flow.
- Phase 4: Authentication, approval matrix, audit history and attachment governance.
- Phase 5: Security upgrades, automated tests, deployment, monitoring and backups.

11. Meeting-day checklist

Check	Action
Database	Start SQL Server LocalDB and verify SparkFinance is accessible.
Original services	Open SparkFinanceBackend.slnx and start the APIs required for the demo.
Accounting	Start AccountingService.API separately because it is not yet in the root solution.
Frontend	Start the Vite frontend and hard-refresh the browser before the meeting.
Data	Keep existing Dubai and India records ready; avoid risky live data entry.
Screens	Verify Dashboard, Exchange Rates, Banking and Chart of Accounts before attendees arrive.
Technical proof	Keep Accounting Swagger available in a separate tab.
Fallback	Keep screenshots available in case a local service or database stops.

Closing statement

End with this

The current system demonstrates the complete operational finance workflow and a controlled, country-specific Chart of Accounts. The next milestone is the accounting engine that turns those operational records into balanced journals, ledgers and management and statutory reports.

What not to claim

- Do not say every screen is live and production-connected.
- Do not say authentication and security are complete.
- Do not say all automated tests pass.
- Do not call the exchange-rate checker an AI agent.
- Do not call the shared-database architecture fully isolated microservices.

Prepared for internal project presentation
